

Lab 2: Joining a network

The purpose of this lab is to configure the network settings of several systems to join one or more networks. This includes setting the IP address, network mask, default gateway, and DNS settings for different distributions of Linux. Once joined, the connectivity will be tested and network traffic observed.

Supplies

• Frodo, Elrond and William VMs (CIS Lab or VLab)

Forum

Use the forum to ask for help, post tips and any lessons learned when you have finished. Forum is at: <u>http://opus.cabrillo.edu/forum/viewforum.php?f=39</u>

Background

For a Linux system to join a LAN (Local Area Network) an IP address and subnet mask must be configured on one of its NIC interfaces. The IP address can be dynamic (obtained automatically from a DHCP server) or static (manually configured IP address). To reach beyond the LAN to the Internet, a default gateway must be configured. To be able to use hostnames, e.g. google.com, rather than numerical IP address a DNS name server must be configured.

The IP and gateway configuration can be configured temporarily (lasts till the next reboot) using the ifconfig and route commands. For a more permanent solution, the IP and gateway information must be added to the appropriate network configuration files in the /etc directory. These files are used by the network service during system startup.

Finally, there are a number of commands (utilities) that can be used to check that traffic is flowing correctly on the networks.

Procedure

You will be cabling Frodo, Elrond and William according to the diagram below. Once cabled you will join the VMs to networks, test connectivity and observe some packet traffic.

Results will be recorded in a lab2 text file that gets submitted at the end of the lab.

Step 1 - Preparation

- □ Revert the VMs back to their "Pristine" snapshots:
 - Frodo
 - Elrond
 - William
- On Opus, make a copy of the lab02 template file in /home/cis192/depot in your home directory.
 Edit the header of this file with your own information.
- □ You may wish to print off the diagram above that is appropriate to where you do this lab. It's nice to have a network diagram handy during a lab to mark up with IP addresses and other notes.

Step 2 - Cabling

- □ Cable each system to the networks shown in appropriate diagram above.
 - Frodo
 - Elrond
 - William

Use the following table to help decide how to make the connections:

	CIS Lab Network	Rivendell Network
VMware Workstation (CIS Lab PCs)	Bridged	VMnet3
VMware ESXi (VLab VMs)	CIS Lab Network	Rivendell

Step 3 - Verify Frodo's connection to the network

In this step we examine the network settings on then Ubuntu VM that gets configured using a DHCP service. The pristine version of Frodo has been preconfigured to connect to the network using DHCP. Snickers, a Windows server in the 2501 closet, provides a DHCP service for room 2501 and the CIS Lab in the CTC. The network settings (IP address, mask, gateway and name server) get configured automatically during system startup.

- Power up Frodo, which is an Ubuntu VM. The goal of Ubuntu is to create an easy-to-use Linux desktop. The Ubuntu distribution is based on Debian.
- □ Login as cis192 and then **sudo -i** to root.
- □ Use **ping -c 3 google.com** to verify we have an IP address, subnet mask, gateway and name server configured. The ping should work.
- Examine the NIC hardware and driver on Frodo:
 - a. Use **lspci** and locate your NIC hardware.
 - b. Try Ispci | grep -i ether instead.
 - c. Use **Ispci -k** and locate your NIC driver.
 - d. Try Ispci -k | grep -iA4 ether to see your NIC driver.
 - e. Use **Ismod** and locate your driver in the output.
- □ Examine the interface:
 - a. Issue the ifconfig command and check that eth0 and lo are up and running.
 - b. lo is the loopback interface to access local services without having to go out on the network.
 - c. For eth0, make sure you can identify the MAC address (HWaddr), IPv4 address (inet addr), IPv6 address (inet6 addr) subnet mask (Mask) and broadcast address (Bcast).
- □ Examine the routing table:

- a. Use **route -n** and look for an entry with 172.30.4.1 under the Gateway column and a "G" under the Flags column. That is the default gateway.
- □ Examine the domain name system (DNS) servers:
 - a. Use **cat /etc/resolv.conf** to show the name servers.
- Record the Frodo network information in your lab02 file.

Step 4 - Frodo trouble-shooting

In this step you are going to break Frodo then fix Frodo.

- □ Use the **rmmod** command to remove the NIC driver.
- □ Verify that you can no longer ping anything.
- □ Without restarting Frodo or reverting to a snapshot see if you can fix Frodo.
- □ Verify that you can ping google.com again.
- Record in your lab02 file what you did to repair Frodo.

Step 5 - Configure Elrond temporarily with static IP addresses

In this step you will be configuring both of Elrond's interfaces with Static IP addresses to match the diagram above.

- Power up Elrond which is running the CentOS Linux distribution. CentOS is a replica distribution of the Red Hat Enterprise Linux distribution.
 - a. Elrond has two NICs so it can be configured as a router in later labs.
 - b. Note that Elrond is configured to boot up to run level 3 (no graphics).
- □ Log in as cis192, then **su** to root.
- □ Clear out any existing name servers with > /etc/resolv.conf
- Try to ping google.com, does it work? It shouldn't.
- □ Try to ping Opus at 207.62.186.9, does it work? It shouldn't.

You shouldn't be able to ping anything because Elrond is configured to boot up without any network settings.

- □ IMPORTANT! Use <u>http://simms-teach.com/docs/static-ip-addrs.pdf</u> to lookup a **non-duplicate** static IP address for Elrond's eth0 interface. This should be based on your station or pod number!
- □ Use **ifconfig eth0 172.30.4**.xxx **netmask 255.255.0** to configure eth0 with that IP address. This is Elrond's interface to the CIS Lab network. This network is in use by other CIS students.
- □ Check local network connectivity:
 - a. Use **ifconfig eth0** to check eth0 is up with your IP address.
 - b. Use **ping 172.30.4.1** to ping the lab router. It should work now.
 - c. Make sure you can ping Frodo too.
- □ Check Internet connectivity:
 - a. Can you ping 207.62.186.9 now? What error do you get?
 - b. We need to specify a router that we can send packets destined for the Internet. This will be our default gateway. Set the default gateway with route add default gw 172.30.4.1 and use route -n to verify. Try pinging 207.62.186.9 again. It should work now.
- □ Check name resolution for the internet:

- a. Can you **ping opus.cabrillo.edu** now? What error message did you get? Without a name server configured the ping command cannot resolve hostnames to IP addresses. Without an IP address, packets cannot be sent to the Internet.
- b. Edit the /etc/resolv.conf file and add the line nameserver 192.168.0.8
- c. Retry pinging opus.cabrillo.edu. This should succeed now that a DNS name server has been configured.
- d. You should be able to **ping google.com** as well. Congratulations ... you just configured your first interface on Linux!
- □ Configure Elrond's second interface.
 - a. Look at the appropriate diagram above and determine what IP address *xxx.xxx.xxx* should be set on eth1. This is Elrond's interface to the Rivendell network.
 - b. Use ifconfig eth1 xxx.xxx.xxx/24 to set that IP address on eth1. It's OK to assign the same IP address to this interface that other students are using on their station or pod. Because no one else can get to your Rivendell network you don't have to worry about having a duplicate IP address.
 - c. Use **ifconfig | more** to check both eth0 and eth1 interfaces are alive and well and using the static IP address you assigned.

Step 6 - Configure Williams Local Area Network interface

In this step you will be configuring William's network settings to match the diagram above.

- Dever up William which is running Windows XP.
- □ Login as cis 192.
- □ Right click on My Network Places and select Properties.
- □ Right click on Local Area Connection and select Properties.
- □ Select Internet Protocol (TCP/IP) and click Properties button.
- □ Select "Use the following IP address:"
- □ Set the IP address to 192.168.2.103
- □ Set the subnet mask to 255.255.255.0
- Don't worry about setting up the default gateway or the DNS name server. Until we learn how to configure routing on Elrond, William will not be able to get out to the Internet. We will learn how to do that in the next lab!
- □ Click OK and close any open dialog boxes.
- □ Start > Run... > cmd to get a command prompt.
- □ Use **ipconfig** to check your static IP was set correctly.
- □ Ping Elrond using **ping 192.168.2.1** which should work.
- □ Try pinging Frodo or the CIS Lab router (172.30.4.1) which should not work.

Step 7 - Traversing the VM's using Putty and SSH

Even though we don't have routes set up between the CIS Lab and Rivendell networks we can still use Putty/SSH to traverse from system to system. Starting with Putty on William you can Putty to Elrond. From there you can ssh to Frodo, and from Frodo you can ssh to opus.cabrillo.edu.

- □ On William, run Putty and login as cis192 on Elrond. What IP address should you use for this? This should be the IP address you put on Elrond's eth1 interface.
- □ Still in Putty, from Elrond, use **ssh cis192@172.30.4.**xxx to login to Frodo. Use **ifconfig eth0** on Frodo if you need to remember Frodo's IP address.

- Still in Putty, from Frodo, use **ssh** *xxxyyy192*@opus.cabrillo.edu to login to Opus using your student account.
- □ Use **who** on Opus to see if anyone else you know is logged on.
- □ Can you ping Frodo from Opus? This should not work and we will learn why in later lessons when we cover NAT/PAT and firewalls.
- Use **exit** to log off Opus.
- Use **exit** to log off Frodo.
- Use **exit** to log off Elrond.

Step 8 - Permanently add static IP addresses on Elrond

We set static IP addresses earlier on Elrond using the ifconfig command. This instantly added the IP addresses to the interfaces. If the system is restarted this configuration information, which is kept in memory, will be lost. In this step we will permanently configure the network settings which is done by editing network configuration files in the /etc directory.

- □ Restart Elrond using **init 6**
- □ Can you ping the Lab router or google.com? You shouldn't be able to because the network configuration, kept in memory, was lost during the system restart.
- □ Edit the **/etc/sysconfig/network-scripts/ifcfg-eth0** file and add the same non-duplicate static IP address you used previously. Use the appendix below for help on this.
- □ Edit the **/etc/sysconfig/network-scripts/ifcfg-eth1** file and add the same static IP address you used previously.
- □ Edit the **/etc/sysconfig/network** file and add the default gateway. Use the appendix below for help on this.
- □ Verify the settings you made in **/etc/resolv.conf** are still there.
- □ Use **service network restart** to restart the network service which will read and apply the information in the network configuration files. The same thing will be done after a system restart.
- □ Use **ifconfig | more** and **route -n** to verify your settings.
- □ Make sure you can ping the William and google.com.
- □ To prove the settings are permanent, use **init 6** to restart the system.
- Record in your lab02 file the four Elrond primary network configuration files and output from ifconfig and route -n. Tip: use redirection to capture the output into a file and use scp to copy that file to your Opus home directory:
 - cat /etc/sysconfig/network-scripts/ifcfg-eth* > notes
 - cat /etc/sysconfig/network >> notes
 - cat /etc/resolv.conf >> notes
 - ifconfig >> notes
 - route -n >> notes
 - scp notes xxxyyy192@opus.cabrillo.edu:

Step 9 - Testing with ping

Do some initial connectivity checks using echo requests (pings):

- On Elrond,
 - Make sure you can ping the loopback address (127.0.0.1), Frodo, William, the CIS Lab router (172.30.4.1) and google.com.

- On Frodo,
 - Make sure you can ping the loopback address (127.0.0.1), Elrond, the CIS Lab router and google.com.
 - Frodo should not be able to ping William or Elrond's eth1 interface. When pinging these Rivendell addresses you will not get an error message. Why not? Because the pings are heading out (the wrong way) to the Internet with no route back. We will learn how to configure routes in Lab 03.
- On William,
 - Make sure you can ping Elrond. William should not be able to ping anything else.

Step 10 - Install some additional commands

We need to install some more commands to do this step:

- On Frodo,
 - Use apt-get install traceroute to install that command.
- On Elrond,
 - Use yum install mtr traceroute tcpdump to install those commands.

Step 11 - Observe where packets go

The **mtr** and **traceroute** commands let you view the route a packet takes. For this lab we will just observer where they go. In future labs we will control where they go.

- On Frodo,
 - Use mtr opus.cabrillo.edu to see the route packets take to Opus.
 - Use **traceroute -I opus.cabrillo.edu** for an alternate view. The -I option on traceroute is to get past the Cabrillo firewalls blocking requests to UDP ports.
 - Use **mtr google.com** to see the route pings take travelling to google.com.
 - Use traceroute google.com for an alternate view.
 - Use **mtr** and **traceroute** with William's IP address (192.168.2.103) to observe why pings never get there.

Step 12 - Sniffing packets with tcpdump

tcpdump is like a command-line version of Wireshark. It allows you to capture packets and view them.

- □ On Elrond,
 - Use **tcpdump -n icmp or arp** to sniff only icmp and arp traffic. The -n prevents doing DNS lookups on IP address to get the hostnames.
 - Use Ctrl-s and Ctrl-q to pause and continue
- On Frodo,
 - Empty Frodo's arp cache with **ip neigh flush all**
 - Ping Elrond and observe the arp request, echo request and echo reply.
- Record in your lab02 file the arp and icmp packets you captured on Elrond when pinging from Frodo.
 Tip: use redirection to capture the output into a file and use scp to copy that file to your Opus home directory:
 - tcpdump -n icmp or arp > capture
 - scp capture xxxyyy192@opus.cabrillo.edu:

To turn in

When finished with this lab, update your total "TBA hours" in your lab02 file. This should reflect the total number of hours you spent preparing for and getting this lab done.

Check your work for completeness then submit as many times as you wish up until the due date deadline. Remember, **late work is not accepted**, so start early, plan ahead for things to go wrong and use the forum to ask questions.

cp lab02 /home/rsimms/turnin/lab02.\$LOGNAME

Grading rubric (30 points)

- 1 points for a correct submittal into the turnin directory
- 2 points for a professional quality lab write-up that can be read using vi
- 2 points for a complete header, including the amount of time you spent on this lab
- 5 points for correct Frodo network information
- 5 points for a correct description of how to repair Frodo
- 5 points for correct Elrond network configuration
- 5 points for correct Elrond ifconfig and route output
- 5 points for correct arp and icmp packet capture

Extra Credit (1 point each)

- 1) Install arpwatch on Elrond and collect at least 10 IP/MAC pairs. Copy your arp.dat file contents to your lab02 file.
- 2) From Frodo, ssh to Elrond using IPv6. Copy the who command output on Elrond to your lab02 file showing the IPv6 address for your session.
- 3) Install Wireshark on Frodo and capture IPv6 pings to Elrond. Be sure to run Wireshark as root. Export the captured packets as text and include one ICMPv6 request and reply to your lab06 file.
- 4) Explain in your lab02 file why Frodo cannot ping William.
- 5) What is the IPv6 address for Opus? Add this to your lab02 file.

Appendix

General Linux commands	
su -	To become root (superuser). The - is very important as it provides root's shell environment.
sudo su -	To become root on the Ubuntu VMs.
or sudo -i	
cp source destination	Linux command to copy file(s) from the source pathname to the destination pathname.
	Example:
	cp /home/cis192/depot/lab01 . will copy the file named lab01 in the /home/cis192/depot directory to your current directory.

vi pathname	Run the vi text editor on the specified
	file.
	Example: vi lab01
who	Show logged in users and the IP address
	or hostnames they logged in from.
echo \$PATH	Shows your path. The shell uses the
	path to locate any commands entered.
	Entering a command that is not located
	on the path will result in a "command
	not found" error.
cat /etc/*-release	Shows the name of the Linux
	distribution being run.
> filename	filename is created if it does not exist
	and emptied.
	Example: > output
	would empty the file named output or
	create it if it did not exist already.
command > filename	<i>filename</i> is emptied, then the output of
	the command is redirected into
	filename.
	Example: ifconfig > output
	would save the output of the ifconfig
	command in a file named output.
command >> filename	Output of the command is appended to
	the end of <i>filename</i> .
	Example: route -n >> output
	would append the routing table to the
	end of the file named output.
ssh account@hostname	Login to a remote Linux computer on
	the network.
<pre>ssh account@xxx.xxx.xxx.xxx</pre>	
	Example:
	ssh cis192@172.30.4.153
<pre>ssh account@hostname 'command'</pre>	Run a command on a remote system.
	Example:
	ssh root@172.30.4.164 'ifconfig'
	would run the ifconfig command on the
	remote system and show the output of
	the command on the local system.
<pre>ssh account@IPv6address%ethn</pre>	ssh works with IPv6 addresses too but
	the outgoing interface being specified.
	ssh
	cis192@fe80::20c:29ff:fe2a:5717ð0
	(all on one line)
<pre>scp pathname account@host:pathname</pre>	Copy files from one system to another.

	Example:
<pre>scp account@host:pathname pathname</pre>	scp output
	simben192@opus.cabrillo.edu:
	(above all on one line)
	would copy the local file named output
	to the user simben192's home directory
	on Opus.
hostname	Shows the hostname of the system
	being used.
tty	Shows the current terminal being used.
exit	End a terminal login session
init 0	A fast way to gracefully shutdown a VM.
	You must be the root user to perform
	this command. Note: no warning is given
	to users that the system will be shut
	down.
yum provides command	Find the package containing the
	command or program to install.
	Example:
	yum provides mail
yum install package	Download and install the software
	package on Red Hat family distributions.
	Just specify the name of the package to
	get the correct version for your
	distribution.
	Examples:
	yum install traceroute
	yum install mtr tcpdump
	yum install mailx
apt-get install package	Download and install the software
	package on Debian family distributions.
	Just specify the name of the package to
	get the correct version for your
	distribution.
	Examples:
	apt-get install traceroute
	apt-get install mtr tcpdump
	apt-get install wireshark ipcalc
VMware commands and operations	1
On <u>PC</u> Keyboard:	Change to a different virtual terminal on
Method 1: While holding down the Ctrl-Alt keys,	the VM. F7 is graphics mode for the
tap spacebar then tap f1, f2, or f7.	Ubuntu VMs. The Centos VMs do not
	have a graphics mode (init level 3 only)
Method 2: While holding down Alt key,	
tap f1, f2, or f7. Does not always work but simpler	Note: the spacebar does not need to be
than method 1.	tapped on a physical (non-VM) system.

	This is just required for changing virtual
	terminals on VMware VMs.
On <u>Mac</u> keyboard:	
Hold down Control and Option keys, tap the spacebar,	
hold down fn key (in addition to Control and Option	
keys) and tap f1, f2, or f7.	
Linux network or network-related commands	
dhclient eth0	Obtain an IP address for the eth0
	interface from a DHCP server.
dhclient -r	Release the IP address previously
	obtained.
ifconfig or /sbin/ifconfig	Show the interface configurations.
	The full absolute pathname may be
	required if user is not logged in as root
	and /sbin is not in the user's path.
ifconfig ethn	Show settings for selected interface.
(where <i>n</i> is the interface number)	
	Example: ifconfig eth1
	will show information on the eth1
	interface.
ifconfig eth <i>n</i> down	Bring an interface down
(where <i>n</i> is the interface number)	
	Example: ifconfig eth1 down
	will disable the eth1 interface.
ifconfig ethn up	Bring an interface down
(where <i>n</i> is the interface number)	
	Example: ifconfig eth1 up
	will enable the eth1 interface.
route -n	Show the current routing table. The -n
	(numerical) option makes it faster. This
	option disables DNS lookups to replace
	ip addresses with nostnames in the
ant (ata/waadu aanf	Show the DNS conversite was for
cat /etc/resolv.com	Show the DNS servers to use for
wing bostsome	Test connectivity with another computer
ping nostnume	an the network like Ctrl C to stop
ping xxx.xxx.xxx	pinging
	pinging.
	The contion can be used to limit the
	number of pipes
	number of hings.
	The bontion can be used to ping a
	hroadcast address
	Example ping -c2 google com will ping
	Example ping -c3 google.com will ping

ping6 -1 ethn IPv6-addressWorks like the IPv4 ping except the outgoing interface must be specified.Example: ping6 -1 ethn fe80::20c:29ff;fe2a:5717mtr hostname or mtr xxx.xxx.xxxDisplays the full route to the host and will refresh travels times.Use q to quitDisplays the full route to the host and will refresh travels times.use q to quitDisplays the full route to the host and will refresh travels times.arp -nDisplays the full route to the host and will refresh travels times.use q to quitDisplays the full route to the host and will refresh travels times.tcpdumpDisplays the full route to the host and will refresh travels times.use q to quitDisplays the full route to the host and will refresh travels times.use q to quitDisplay arp cachearp -nDisplay arp cachetcpdumpWill start sniffing packets.http://www.alexonlinux.com/tcpdump- for-dummiestcpdump -n arp or icmpPacket sniffing command to capture only arp and icmp packetsUse -n to prevent DNS lookups Use Ctrl-s or Ctrl-q to pause and continuePacket sniffing command to capture only traffic between two hosts.use Ctrl-s or Ctrl-q to pause and continueExample: tcpdump -n host 172.30.4.25 and host tr2.30.4.1 (all on one line)tcpdump -ne -i ethn port nn or port nnExample: tcpdump -ne -i eth1 port 80 or port 22 • no DNS lookups (-n) • shows mac addresses (-e) • will listen on eth1 interface (-i eth1) • only captures ssh and http traffic (port 80 or 22)		Google three times then stop.
outgoing interface must be specified.Example: ping6 -1 eth0 fe80::20c:29ff:fe2a:5717mtr hostname or mtr xxx.xxx.xxxDisplays the full route to the host and will refresh travels times.Use q to quitDisplays the full route to the host and will refresh travels times.Use q to quitDisplays the full route to the host and will refresh travels times.arp -nDisplays the full route to the host and will refresh travels times.use q to quitDisplays the full route to the host and will refresh travels times.tcpdumpVill start sniffing packets.tcpdump - n arp or icmpPacket sniffing command to capture only arp and icmp packetsUse - n to prevent DNS lookupsPacket sniffing command to capture only arp and icmp packetsuse Ctrl-s or Ctrl-q to pause and continueExample: tcpdump - n host 172.30.4.25 and host 172.30.4.1 (all on one line)tcpdump - ne - i ethn port nn or port nnExample: tcpdump - ne - i eth1 port 80 or port 22 • no DNS lookups (-n) • shows mac addresses (-e) • will listen on eth1 interface (-i eth1) • only captures ssh and http traffic (port 80 or 22)	ping6 -I ethn IPv6-address	Works like the IPv4 ping except the

Interface configuration (temporary, till next restart)	Interface configuration (temporary, till next restart)	
ifconfig ethn xxx.xxx.xxx netmask xxx.xxx.xxx Configure an interface with an IP	ifconfig ethn xxx.xxx.xxx netmask xxx.xxx.xxx	Configure an interface with an IP
address and subnet mask.		address and subnet mask.
where <i>n</i> is the interface number and <i>xxx.xxx.xxx</i> is	where <i>n</i> is the interface number and <i>xxx.xxx.xxx.xxx</i> is	
the dotted decimal form of the IP address or netmask Example:	the dotted decimal form of the IP address or netmask	Example:
ifconfig eth0 172.30.4.149 netmask		ifconfig eth0 172.30.4.149 netmask

	255.255.255.0
	(all on one line)
	Would configure eth0 with that IP
	address and mask.
ifconfig ethn xxx.xxx.xxx./pp	Same as previous command but the
č	subnet mask is specified instead using a
where <i>n</i> is the interface number. <i>xxx.xxx.xxx.xxx</i> is the	CIDR network prefix.
dotted decimal form of the IP address and pp is the	· ·
network prefix	Example: ifconfig eth0 172.30.4.149/24
ip address flush dev ethn	Removes all settings from the selected
(where <i>n</i> is the interface number)	interface.
(
	Example: ip address flush dev eth0
	will remove all interface settings
	including the IP address from eth0
Red Hat interface configuration (permanent)	including the in dudiess, non-etho.
Edit /etc/sysconfig/network-scripts/ifcfg_ethn	Each interface has an associated ifcfg-
and add or modify these lines:	ethe file in the lot /sysconfig/network
and add of modify these lines.	scripts directory
	scripts unectory.
	These files are used at system startup to
	mese mes are used at system startup to
	comigure the interfaces.
NETWASK= XXX.XXX.XXX.XXX	Set NM_CONTROLLED to yes or no
	to use or not use Red Hat
Example 1 - ethU is not configured:	NetworkManager utility.
/etc/sysconfig/network-scripts/ifcfg-eth0	
DEVICE="eth0"	Set ONBOOT to "yes" to bring up the
NM_CONTROLLED="yes"	interface or "no" to disable the interface
ONBOOT="no"	at system startup.
Example2 - eth0 has a static IP configured:	Set BOOTPROTO to "static" to configure
/etc/sysconfig/network-scripts/ifcfg-eth0	a static IP address or "dhcp" to configure
DEVICE="eth0"	a dynamic IP address.
NM_CONTROLLED="no"	
ONBOOT="yes"	For static IP addresses, set IPADDR to
BOOTPROTO="static"	the static IP address. Be sure this is a
IPADDR=172.30.4.149	unique IP address for your system to
NETMASK=255.255.255.0	avoid duplicate IPs on the network! Set
	NETMASK to the subnet mask.
Example 3 - eth0 is configured for DHCP:	
<pre>/etc/sysconfig/network-scripts/ifcfg-eth0</pre>	
DEVICE="eth1"	
NM_CONTROLLED="no"	
ONBOOT="yes"	
BOOTPROTO="dhcp"	
For the new interface settings to take effect without	

restarting the system, use:	
service network restart	
or /etc/init.d/network restart	
Routing table configuration (temporary, till next restart)	
route add default gw xxx.xxx.xxx	Adds the default gateway to the routing
	table. Unless there is another more
where xxx.xxx.xxx is the dotted decimal form of the	specific route in the routing table this is
IP address for the default gateway router.	the route will be used to send outbound
	packets.
	Example:
	route add default gw 172.30.4.1
	adds the lab router as the default
	gateway.
route del default gw xxx.xxx.xxx.xxx	Deletes the default gateway in the
where xxx xxx xxx xxx is the dotted decimal form of the	routing table.
IP address for the default gateway router.	Example:
	route del default gw 172.30.4.1
	deletes the lab router as the default
	gateway.
Red Hat routing table configuration (permanent)	
Edit (e.g. with vi) the /etc/sysconfig/network file and	Edit this file to add a permanent default
add or modify:	settings do not take effect until the
GATEWAY= xxx.xxx.xxx.xxx	system or network service is restarted.
	-,
where xxx.xxx.xxx.xxx is the dotted decimal form of the	
IP address for a router.	
Evennler	
example: /etc/sysconfig/network	
NETWORKING=ves	
HOSTNAME=elrond.localdomain	
GATEWAY=172.30.4.1	
The default gateway on Elrond has been set to the CIS	
Lab router (172.30.4.1).	
For the new interface settings to take effect without	
For the new interface settings to take effect without restarting the system. use:	
For the new interface settings to take effect without restarting the system, use: service network restart	
For the new interface settings to take effect without restarting the system, use: service network restart or /etc/init.d/network restart	
For the new interface settings to take effect without restarting the system, use: service network restart or /etc/init.d/network restart	

Edit (e.g. with vi) the /etc/resolv.conf file and add one	Use this file to specify one or more DNS
or more	server. The first server listed will be the
nameserver xxx.xxx.xxx.xxx	primary name server. The second will
lines to specify DNS servers for name resolution	be the secondary name server and so
services.	forth.
where <i>xxx.xxx.xxx.xxx</i> is the dotted decimal form of the	Example:
IP address for a DNS name server.	<u>/etc/resolv.conf</u>
	nameserver 192.168.0.8
	nameserver 10.240.1.2
	configures the CIS VLab DNS server
	(192.168.0.8) as the primary and the
	campus DNS server (10.240.1.2) as the
	secondary.
>/etc/resolv.conf	Clears all DNS name servers
Linux hardware and driver commands	1
echo 0 >	Enables Linux system to respond to
/proc/sys/net/ipv4/icmp_echo_ignore_broadcasts	broadcast pings.
Ispci	Shows PCI devices including what NIC or
	NICs (Network Interface Controllers) are
or /sbin/lspci	being used to physically connect the
	system to the network.
	The full absolute pathname may be
	required if user is not logged in as root
	and /sbin is not in the user's path.
	Frample:
	Isnci I gren -i ether
	will show all the ethernet NICs on the
	system.
lspci -k	Show the drivers kernel modules used
	by the PCI devices including any NICs.
	Example:
	lspci -k grep -iA4 ether
	will show the drivers used by the NICs
	on your system.
Ismod	Shows the kernel modules that are
	currently loaded. Example NIC drivers
or /sbin/lsmod	(implemented as kernel modules) are
	e100 (Intel), e1000 (Intel), pcnet32
	(AMD) and vmxnet (VMware).
	The full absolute pathname may be
	required if user is not logged in as root

	and /sbin is not in the user's path.
rmmod module	Use to unload (remove) a running kernel
	module (e.g. a NIC driver).
	Example: rmmod e1000 would unload
	the Intel gigabit NIC driver if it was
	loaded.
modprobe module	Use to load a kernel module (e.g. NIC
	driver).
	Example: modprobe e1000 would load
	the Intel gigabit NIC driver if not loaded
	already.
